METADATA

I. CLASS I. Data Set Descriptors

A. Data set identity: Demographic data from populations of the understory herb *Heliconia acuminata* (Heliconiaceae) in an experimentally fragmented tropical landscape (1997-2013).

B. Data set identification code:

1. Dataset File 1: `HDP_plots.csv`
2. Dataset File 2: `HDP_1997_2009.csv`

C. Data set description:

1. **Originators:** Emilio M. Bruna, Department of Wildlife Ecology and Conservation, University of Florida, PO Box 110430, Gainesville, FL 32611-0430, USA and Center for Latin American Studies, University of Florida, PO Box 115530, Gainesville, FL 32611, USA.

2. **Abstract:** Habitat fragmentation is thought to be a leading cause of extinction, but the demography of species in fragmented landscapes remains poorly understood. This is particularly true in tropical ecosystems, where studies monitoring populations of species in both fragments and areas of continuous habitat across all life-history stages are virtually nonexistent. Here we report 12 years (1997-2009) of annual censuses of 13 populations of the Amazonian understory herb *Heliconia acuminata* (LC Rich.). These surveys were conducted in plots established in the experimentally fragmented landscape of the Biological Dynamics of Forest Fragments Project, located north of Manaus, Brazil. The plots, each 50 x 100 m, are located in forest fragments of different sizes (N = 4 plots in 1-ha fragments and N = 3 plots in 10-ha fragments) as well as continuous forest (N = 6 plots). The population in each plot was censused annually, at

which time we recorded identified, marked, and measured new seedlings, identified any previously marked plants that had died, and recorded the size of individuals that survived. During the flowering season we conducted regular surveys to recorded the identity of flowering plants and the number of inflorescences each produced. The resulting dataset comprises >67000 plant x year records of N = 8586 plants, including N = 3464 seedlings that became established after the initial census. These data have been used in publications on topics ranging from how fragmentation-related reductions in germination influence population growth rates to tests of statistical methods for analyzing reproductive rates.

D. Key words: Amazon, Brazil, deforestation, demography, edge effects, flowering, forest fragments, habitat fragmentation, integral projection models, matrix models, population dynamics, vital rates.

CLASS II. RESEARCH ORIGIN DESCRIPTORS

A. Overall project description:

1. **Identity:** The *Heliconia* Demography Project

2. **Originators:** Emilio M. Bruna, W. John Kress, and María Uriarte

3. **Period of study:** 1997-2009

4. **Objectives:** Habitat fragmentation continues to be a major focus of research by ecologists (Didham et al. 2012, Haddad et al. 2015, Brudvig et al. 2017, Resasco et al. 2017, Fletcher et al. 2018) decades after it was first identified as a threat to the integrity of ecosystems (Harris 1984, Wilcove et al. 1986). A large body of empirical research has documented myriad biotic changes associated with fragmentation, including the local extinction of plant species from fragments (Harrison and Bruna 1999, Laurance et al. 2011). Although the demographic mechanisms underlying these

extinctions are rarely known (Bruna et al. 2009), they are often hypothesized to result from reduced rates of individual growth, reproduction, or survivorship in fragments (Laurance et al. 1998, Zartman et al. 2015). This is especially true tropical forest fragments, where abiotic conditions can be dramatically different from those in primary forest (reviewed in Broadbent et al. 2008). Tests of this hypothesis remain limited, however, by the paucity of long-term demographic data collected in both tropical forest fragments and continuous forest sites (Bruna et al. 2009).

Most studies investigating the effects of forest fragmentation on tropical plants focus on trees (Cordeiro et al. 2009, Jurinitz et al. 2013, Zambrano and Salguero-Gómez 2014), in part because they are major reservoirs of carbon (Slik et al. 2010, Lasky et al. 2014). However, herbaceous species can comprise up to 30% of the plant species in lowland tropical forests (Gentry and Emmons 1987, Ribeiro et al. 2010, Iannone and Vargas 2022, Spicer et al. 2022), where they are habitat and food for myriad animal taxa and economically and culturally vital non-timber forest products (Nakazono et al. 2004, de Athayde et al. 2006). Despite their biocultural importance, however, the way in which habitat fragmentation and other global change phenomena influences the population dynamics of tropical understory plants remains conspicuously understudied (Bruna et al. 2009).

The *Heliconia* Demography Project (HDP) was established to address the lack of data on the demography of understory plants in fragmented tropical landscapes. The core of the HDP is annual censuses of thirteen populations of *Heliconia acuminata* located in either continuous forest or experimentally isolated forest fragments at Brazil's Biological Dynamiocs of Forest Fragments Project (Laurance et al. 2011) The primary purpose behind their initial collection was to parameterize size-structured demographic models (Caswell 2000, Ellner and Rees

2006) with which to (1) compare the demography and population dynamics of *H. acuminata* populations in fragments and continuous forest, and (2) test the hypothesis that reductions in seedling establishment in forest fragments would lead to population declines.

5. **Abstract:** Here we report 12 years (1997-2009) of annual censuses of 13 populations of the Amazonian understory herb *Heliconia acuminata* (LC Rich.). These surveys were conducted in plots established in the experimentally fragmented landscape of the Biological Dynamics of Forest Fragments Project, located north of Manaus, Brazil. The plots, each 50 x 100 m, are located in forest fragments of different sizes (N = 4 plots in 1-ha fragments and N = 3 plots in 10-ha fragments) as well as continuous forest (N = 6 plots). The population in each plot was censused annually, at which time we recorded identified, marked, and measured new seedlings, identified any previously marked plants that had died, and recorded the size of individuals that survived. During the flowering season we conducted regular surveys to recorded the identity of flowering plants and the number of inflorescences each produced. The resulting dataset comprises >67000 plant x year records of N = 8586 plants, including N = 3464 seedlings that became established after the initial census. These data have been used in publications on topics ranging from how fragmentation-related reductions in germination influence population growth rates to tests of statistical methods for analyzing reproductive rates.

6. **Sources of funding:** The initial establishment of plots and the 1998-2002 surveys were supported by grants to E. M. Bruna from the Smithsonian Institution (Graduate Student Research Award), the University of California, Davis (Center for Population Biology Graduate Research Grant, M. E. Mathias Graduate Research Grant), the Biological Dynamics of Forest Fragments Project (Graduate Student Logistics Grant), the National Science Foundation (Dissertation Improvement Grant INT 98-06351), and

the Ford Foundation (Dissertation Year Fellowship). The 2001-2005 surveys were supported a grant from the National Science Foundation to E. M. Bruna (Research Starter Grant DEB-0309819). The 2006-2009 surveys were supported by grants from the National Science Foundation to E. M. Bruna (DEB-0614149) and María Uriarte (DEB-0614339). Subsequent analyses and the preparation of these data for archiving were supported by the National Science Foundation (DEB-1948607).

B. Subproject description

1. Site description

a. **Site type:** Lowland tropical forest

b. **Geography:** The data were collected at the Biological Dynamics of Forest Fragments Project (BDFFP, 2°30'S, 60°W), a 1000-km mosaic of lowland forest, forest fragments, secondary forests, and pastures located approximately 70 km north of Manaus, Amazonas, Brazil (Fig. 1).

c. **Habitat:** The BDFFP is dominated by tropical evergreen lowland forest (i.e., 'tropical moist forest', *sensu* Holdridge (1967). The forest canopy at the sites is ~35–40 m tall, with emergent trees of up to ~45 m (Rankin-de-Mérona et al. 1992-Oct-Dec). The tree community at the BDFFP is highly diverse: ~1300 species total (Laurance 2001), with as many as 280 tree species ha^{-1} (de Oliveira and Mori 1999). The understory is dominated by stemless palms (Scariot 1999). All HDP plots are located in *terra-firme* (i.e., non-flooded) forest and none are bisected by streams.

d. **Geology:** Soils in the sites are nutrient-poor xanthic ferralsols, known as yellow latosols in the Brazilian soil classification system. Despite their high clay content they have poor water-retention capacity (Fearnside and

Leal-Filho 2001). The often rugged topography at the BDFFP ranges in elevation from 50-150 m elevation (Gascon and Bierregaard 2001).

e. **Watersheds:** The BDFFP landscape includes catchments of the Urubu, Cuieiras, and Preto da Eva rivers (Nessimian et al. 2008).

f. **Site history:** A complete history of the BDFFP can be found in Gascon and Bierregaard (2001) and Bierregaard et al. (2002). Briefly, the BDFFP reserves were established on three cattle ranches. Fragments were isolated between 1980-1984 by felling the trees surrounding the patch of forest to be isolated (Lovejoy et al. 1986). Fragment reserves were fenced to prevent the incursion of cattle from the surrounding pastures. To ensure fragments remain isolated, a 100m strip around each fragment is regularly cleared of the secondary growth (Gascon and Bierregaard 2001). The structure and species composition of the secondary growth that surrounds a fragment, which is strongly dependent on whether fire was used to clear land prior to planting pasture grasses (Mesquita et al. 2001), can have large effects on the species composition, ecological processes, and abiotic conditions in fragments (reviewed in Laurance et al. 2002, 2011). The BDFFP is currently administered collaboratively by the Smithsonian Tropical Research Institute and Brazil's Instituto Nacional de Pesquisas da Amazônia (INPA).

g. **Climate:** Mean annual temperature at the site is 26°C (range 19-39°C). Annual rainfall ranges from 1900-2300 mm (Scott et al. 2021), with a pronounced dry season from June-December in which there is <100 mm rain per month.

2. **Sampling Design & Research Methods**

a. **Focal species:** *Heliconia acuminata* (Heliconiaceae) is a perennial,

self-incompatible monocot native to Amazonia (Kress 1990) and widely distributed throughout the Amazon basin (Kress 1990). Although many species of *Heliconia* grow in large aggregations on roadsides, gaps, and in other disturbed habitats, others, including *H. acuminata*, grow primarily in the shaded forest understory (Kress 1983). *Heliconia acuminata* is the most abundant understory herb throughout much of the BDFFP (Ribeiro et al. 2010); the other two *Heliconia* species found in the BDFFP reserves are either very rare (*H. latispatha*) and restricted saturated soils adjacent to streams (*H. tarumaensis*).

Each *Heliconia acuminata* has a basal rhizome from which emerge erect vegetative shoots with broad leaves, as well as one or more flowering shoots if the plant is reproductive. Plants grow slowly (Bruna and Ribeiro 2005) and the proportion of plants that flower is low (Gagnon et al. 2011). The primary herbivores of *Heliconia* species are Hispine beetles, whose larvae and adults scrape the surface of unrolled immamture leaves (Strong 1977). The beetle species associated with *H. acuminata* is *Cephaloleia nigriceps* Baly (Staines and Garcia-Robledo 2014); it actually does little damage to leaves but can cause extensive damage to bracts, flowers, and developing ovaries.

Heliconia can be propagated by segmenting the rhizome (Berry and Kress 1991, Bruna and de Andrade 2011), and clonal spread is common in the *Heliconia* species found in open or disturbed habitats (Schleuning et al. 2008). However, recruitment in *H. acuminata* and other understory species is primarily via seeds (Bruna 1999, 2002). Plants that flower do so during the rainy season, with the propbability of flowering increasing with plant size (Bruna and Kress 2002). The

overwhelming majority of plants that flower (75%) produce just one infloresence (range = 1-7), each of which has on average 22.28 ± 1.17 SE flowers (range 4-62) that remain open for one day before falling from the plant. Pollen transfer experiments indicate self-compatibility is extremely low (Bruna and Darrigo, *unpubl. data*); succesfully pollinated flowers can produce 1-3 seeds, with an average of 2 seeds per fruit (Bruna and Kress 2002).

Heliconia acuminata is pollinated by the 'traplining' hummingbirds *Phaeothornis superciliosus* and *P. bourcieri*. Visitation rates to flowers are extremely low (<1 visit hour^{-1}, Bruna et al. 2004), as are rates of fruit production (Bruna and Kress 2002). The fleshy blue fruits are consumed by birds (Uriarte et al. 2011); in our study sites the primary dispersers are the White-necked Thrush (*Turdus albicollis*), the Thrush-like-Manakin (*Schiffornis turdinus*), and several species of manakin (*Pipra erythrocephala*, *P. pipra*, *Lepidothrix serena*, and *Corapipo gutturalis*). The seeds germinate 6-7 months after dispersal, which coincides with the onset of the rainy season (Bruna 1999, 2002). Post-dispersal seed predation is negligible. Experiments revealed that few *H. acuminata* seeds germinate after one year unless protected from burial under leaf-litter (Bruna 1999, 2002), which is consistent with the generalization that few plant species in lowland tropical forests have seed banks .

b. **Taxonomy, systematics, and voucher specimens:** *Heliconia* is the only genus in the family Heliconiaceae. This family is distinguished from the others in the order Zingiberales by inverted flowers, having a single staminode, and fruits that are drupes. It is estimated that there are 200-250

species of *Heliconia*, almost all of which are native to the Neotropics. *Heliconia acuminata* L. C. (Rich.) (Richard 1831) is one of the approximately 20 *Heliconia* species found in the Brazilian Amazon (Kress 1990). We deposited voucher specimens of *H. acuminata* collected in areas adjacent to demographic plots at the herbaria of the Instituto Nacional de Pesquisas da Amazônia (Accession Numbers INPA 189569-189573) and the University of California, Davis (Accession Numbers DAV 69391-69396).

c. **Permanent Plots:** Surveys of *Heliconia acuminata* demography were carried out in 13 permanent demographic plots distributed across the BDFFP landscape (Bruna and Kress 2002). Six plots are in continuous forest, four are in 1-ha fragments, and three are in 10-ha fragments (Fig. 1). Each demographic plot is 50m x 100m and is subdivided into 50 contiguous subplots of 10 x 10 m to facilitate the surveys. Plots in 1-ha fragments were established in a randomly selected half of the fragment, plots in 10-ha fragments are located in the center of the fragment, and plots in continuous forest are located 500-4000 m from any borders with cattle pastures or secondary forest (Fig. 2). The plots furthest apart are from each other are separated by ~70 km.

Plots 1-ha fragments, 10-ha fragments, and three of the continuous forest sites were established from January-April 1997, the remaining three plots in continuous forest were established in January 1998. To mark the plants, a team of 2-3 people slowly walked through each subplot and located all *Heliconia acuminata* and marked them with a wooden stake to which was attached an individually numbered aluminum tag. The size of each plant was measured in two ways: (1) by counting its number of vegetative shoots and (2) by measuring the

height of the plant from the ground to the top of its highest leaf (rounded to the nearest cm). Three additional plots were established in continuous forest sites in 1998 (CF 4-6); all plants in these plots were tagged and measuring in the same way as in other plots.

d. **Frequency of Data Collection** Plots were censused annually at the onset of the rainy season to coincide with seedling establishment (generally late January to February). The exception to this was the three continuous forest plots established in August 1998, which were censused in August 1999. During each census team members recorded which plants died, the size (i.e., height and number of shoots) of all surviving plants, and the size of all new seedlings, which were also marked with a numbered tag. Regular visits were made to all 13 plots throughout the rainy season to identify reproductive individuals, at which time we recorded the number of inflorescences.

3. **Project personnel:** In addition to the Originators, other key personnel include the Project Managers that were responsible for coordinating the annual censuses and other field activities, BDFFP Technicians (*"Mateiros"*) that assisted with data collection and provided logistical support in the field, and undergraduate and postgraduate field assistants hired to assist with the surveys.

a. **Project Managers:** Paulo Rubim (2007-2012), Maria Beatriz Nogueira (2002), Maria Rosa Darrigo (2002-2003), Cris Follman Jurinitz (2003), Simone Benedet (2004).

b. **BDFFP Technicians:** Osmaildo Ferreira da Silva, Francisco Marques, Alaercio Marajó dos Reis, João de Deus Fragata, Romeu Cardoso.

c. **Undergraduate & Postgraduate Field Assistants:** Olavo Nardy (2000), Obed Garcia (2001), Sylvia Heredia (2001-2002), Maria Beatriz

Nogueira (2002), Cris Follman Jurinitz (2003), David M. Lapola (2003), Denise Cruz (2003), Cristina Escate (2004), Bruno Turbiani (2005), Elisabete Marques da Costa (2006), Wesley Dáttilo da Cruz (2007), Jefferson José Valsko da Silva (2007).

CLASS III. DATA SET STATUS AND ACCESSIBILITY

A. Status

1. **Latest update:** 2022-05-24

2. **Latest archive date:** 2022-05-24 *(to replace with date of archiving at Dryad)*

3. **Metadata status:** Complete (last update: 2022-07-19)

4. **Data verification & quality control procedures:** An extensive review of the data was conducted prior to the dataset's archiving. We began by generating a list of potential anomalies that could indicate errors (e.g. extremely large changes in size from one year to the next, plants marked as dead that had subsequent measurments), and then wrote code to search for these anomalies using the R statistical programming language (Team 2014). We also used the `pointblank` library (Iannone and Vargas 2022), which similarly identifies cases in a dataset for review and validation. All records flagged were evaluated by E. M. Bruna by checking the values in the electronic records against the original data sheets. Any necessary corrections to the dataset were also made using R scripts; the code for these changes and for preparing the datasets for archiving is archived at Zenodo [url to be added]. Questions from future users of the database should be referred to E. M. Bruna, who will investigate and update the database as needed. Code for any post-archiving updates is maintained at Github (https://github.com/BrunaLab/HeliconiaDataPaper).

B. Accessibility

1. **Storage location and medium:** Ecological Society of America Data Archives [url to be added] and the Dryad Digital Repository [url to be added].

2. **Location of original data forms, electronic files, and archived copies:** Original data sheets and electronic data files are stored at the University of Florida. Original data files and paper copies are stored in separate locations, with electronic copies of data sheets (.pdf format) and electronic data files (.csv and .xlsx format) are stored on a desktop computer, a synced institutional cloud storage account, and a portable hard drive. The integrity of digital files is verified semi-annually.

3. **Contact person(s):** Emilio M. Bruna, Department of Wildlife Ecology and Conservation, Box 110430, Gainesville, FL 32611 USA. Phone: (352) 846-0634. Email: embruna@ufl.edu

4. **Copyright restrictions:** None

5. **Proprietary Restrictions:**

    a. **Proprietary restrictions:** None.

    b. **Conditions of Reuse:** Any publication using data collected at the BDFFP must include a BDFFP Technical Series Number in the Acknowledgments. Authors can request a series number upon the acceptance of their article by contacting the BDFFP's Scientific Coordinator or E. M. Bruna.

    c. **Citation:** Authors of any publications or products using these data cite should the data paper and data archive as per *Ecological Archives* and *Dryad* policy. We also request that they provide E.M. Bruna a copy of their article upon acceptance, which allows us to track the dataset's usage, inform users of any corrections or updates, report articles using the data to the funding agencies that provided support, and document that different

ways in which the scientific community uses the data.

d. **Disclaimers:** While the data are provided in good faith and are accurrate to the best of our knowledge, they are provided "as is". We do not assume any legal liability or responsibility for their accuracy, completeness, or utility. The responsibility for use and analysis of these data lies completely with the user.

CLASS IV. DATA STRUCTURAL DESCRIPTORS

A. Dataset File 1: Descriptors of demographic plots

1. **Identity:** `HDP_plot_descriptors.csv`
2. **Size:** 14 rows (including header), NA bytes.
3. **Format and storage mode:** ASCII text, comma delimited. No compression scheme used.
4. **Header information:** The first row of the file contains the variable names.
5. **Alphanumeric attributes:** Mixed
6. **Special Characters:** Missing values are represented with NA.
7. **Authentication Procedures**: checksum (MD5:2d3ec96006667abab1ecc14e72055850)
8. **Start & End Columns:** Start: `plot`, End: `yr_isolated`
9. **Variable Information:** Each row is one plot, with the columns providing plot-specific values for each variable.

334 **[INSERT TABLE 1 HERE]**

335 **B. Dataset File 2:** *Heliconia* Demographic Data

336 1. **Identity:** `HDP_data_1997-2009.csv`

337 2. **Size:** 66785 rows (including header), 3.79 kilobytes.

338 3. **Format and storage mode:** ASCII text, comma delimited. No compression scheme
339 used.

340 4. **Header information:** The first row of the file contains the variable names.

341 5. **Alphanumeric attributes:** Mixed.

342 6. **Special Characters:** Missing values are represented with NA.

343 7. **Authentication Procedures**: Checksum (MD5:15bbb4869fe192649e93d3474d3145d1)

344 8. **Start & End Columns:** Start: `plot`, End: `tag_number`

345 9. **Data anomalies:** Following each survey, the measurements of plant height and stem
346 number were compared with those from the previous year to identify potential errors in
347 either plant measurement or entry (e.g., a plant with 1 shoot in year t and 11 shoots in
348 year t+1 is likely an error in data entry). Discrepancies were investigated by referring
349 to the original data sheets and, on occasion, returning to the field to remeasure plants.

350 Plants that could not be found during a survey were recorded as 'missing' but
351 maintained on the survey list to be searched for in subsequent years. The same is
352 true of plants under branches or the crowns of fallen trees, which might not be
353 found for several years when the crown's leaves dried and fell or the area under
354 the crown could be safely searched. The codes used to denote such cases are
355 defined in Table 2.

The stakes and numbered tags used to mark plants were sometimes displaced, broken, or buried under leaf litter as a result of tree falls or other disturbances. If a tag couldn't be found after an extensive search, the plant would be marked with a new tag number. In some cases, determining such a plant's original number was straightforward (e.g., all plants in a low-density subplot were found except one, which in the prior year was similar in size as the plant found without a tag). In those cases, the plant's prior measurements were transferred to the new number and we logged the details of the tag number transfer (e.g., old number, new number, year; the latest version of the log is archived at [zenodo url to be added]. In other cases, however, it was impossible to definitively determine a plant's original number (e.g., when two adjacent and similarly sized plants were both missing their tags). In these cases the original number was maintained in the database with the plant's status noted as 'missing' in subsequent surveys. The record for the new number indicates the plant with which it is associated is an established plant that was found without a tag (and not a new seedling; see Section IV and Table 2). There were also cases in which established plants were found without tags in subplots where all previously tagged plants had already been located and measured (i.e., previous survey teams failed to find and mark the plants). These plants were also marked, measured, and added to the database as an established but unmarked plant. Of the N = 947 plants in the dataset, 11% were found without tags after the plot had been established. Almost half of these (49%) were in the three plots where *H. acuminata* density was highest (CF-1, FF-7, CF-3).

Finally, no survey was conducted in plot CF-6 (Cabo Frio, Continuous Forest) in 2003 due to logistical constraints.

8. **Variable information:** Each row in the data set is a demographic plot, with columns

of data describing that plot. Blanks do not denote missing information, but rather nothing relevant to report.

[INSERT TABLE 2 HERE]

CLASS V. SUPPLEMENTAL DESCRIPTORS

A. **Computer programs and data-processing algorithms:** The code used to process the data and prepare it for archiving is archived at Zenodo [url to be added] and available for continuous improvement at Github (https://github.com/BrunaLab/HeliconiaDataPaper). The Github repository also includes the up-to-date list of tag changes and any corrections to the dataset made after its archiving.

B. **Publications and results:** The following articles have included analyses of part or all of the dataset. An update list can be found in the HDP's Github repository (https://github.com/BrunaLab/HeliconiaDataPaper).

465 **ACKNOWLEDGMENTS**

466 This work would not have been possible without the technicians and field assistants
467 participating in the annual surveys, the logistical support provided by the BDFFP staff, and
468 the organizations providing financial support. Sharon Y. Strauss, Susan P. Harrison, and
469 Patricia Delamônica Sampaio provided invaluable feedback during the project's
470 establishment. Charles L. Staines identified the Hispine beetle. This paper is publication
471 number – – in the BDFFP Technical Series.

Variable	Definition, Units, and Precision	Codes	Storage
plot	Code used to identify a plot	FF1-FF7: plots in fragments CF1-CF6: plots in continuous forest	string
habitat	Habitat type in which a plot is located	one: 1-ha fragment ten: 10-ha fragment forest: continuous forest	string
ranch	Ranch in which a plot is located	Porto Alegre, Esteio, Dimona	string
bdffp_no	The BDFFP Reserve Number for the reserve in which plot is located	2017, 2018, 1104, 1301, 2206, 1202, 3209, 1501, or 'none' (for plots outside BDFFP reserve boundaries)	string
yr_isolated	Year in which a fragment was initially isolated	1980, 1983, 1984	integer

Variable	Definition	Codes	Range	Storage
plot	Plot in which plant is located	FF1-FF7 CF1-CF6	-	string
subplot	Subplot in which plant is located	A1-A10, B1-B10, C1-C10, D1-D10, E1-E10, (CF3 only: F6-F10, G6-G10, H1-H10, J1-J10)	-	string
plant_id	Unique ID number assigned to plant	-	1-8660	integer
year	Calendar year of survey	-	1998-2009	integer
shts	No. of shoots when surveyed (Units: shoots; Precision: 1)	-	0-24	integer
ht	Plant height when surveyed (Units: cm; Precision: 1)	-	0-226	integer
infl	If reproductive, the no. of inflorescences (Units: Infloresences; Precision: 1)	-	1-7	integer
recorded_sdlg	Whether plant was new seedling in a survey year	TRUE = seedling FALSE = not a seedling)	-	logical
found_without_tag	Whether plant was found without tag during a survey	TRUE = established plant with no tag FALSE = seedling or previously marked plant	-	logical
census_status	Status in a census	measured = plant alive, measured dead = plant died between this and prior census missing = plant not found in census	-	string

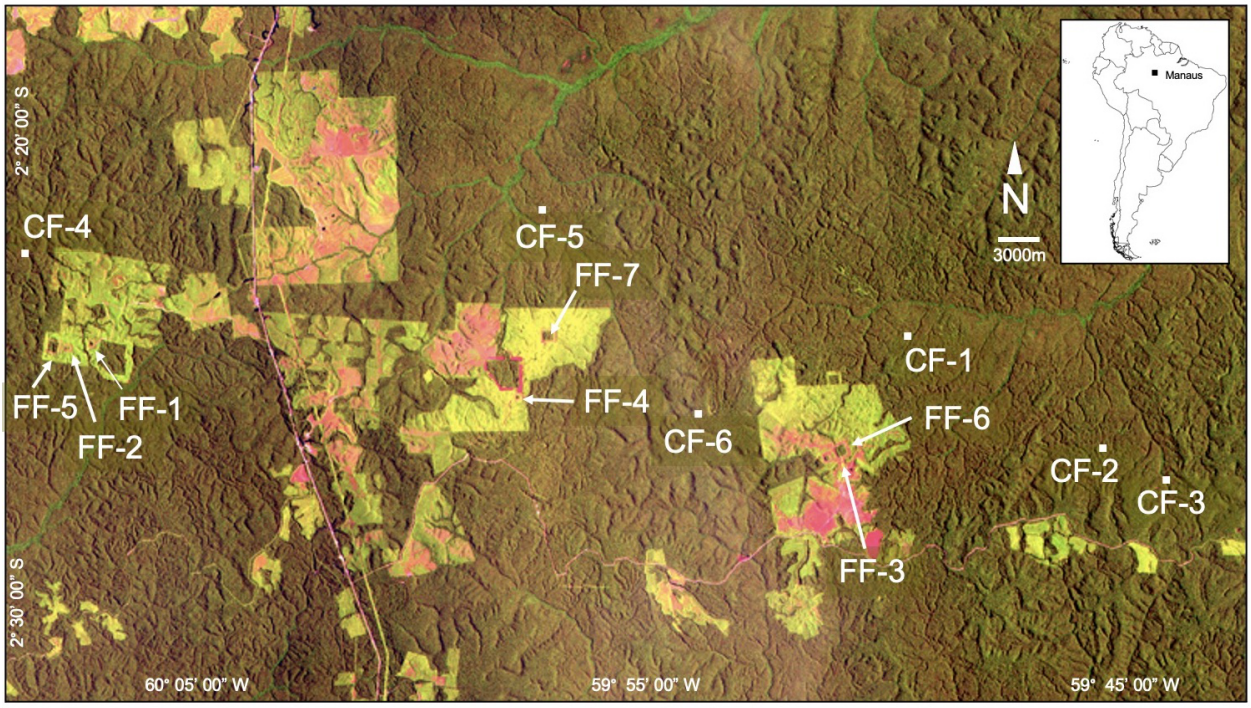

Figure 1. Satellite image (est. 1997) of the Biological Dynamics of Forest Fragments Project showing the location of the *Heliconia* Demographic Plots. Plots are located in Continuous Forest (CF1-CF6) or Forest Fragments (FF1-FF7). Dark green is primary forest, light green is regenerating forest, and red indicates pasture and recently cleared areas. The BDFFP is located 70 km north of Manaus, Brazil (inset map); for additional details on each plot see Table 1.

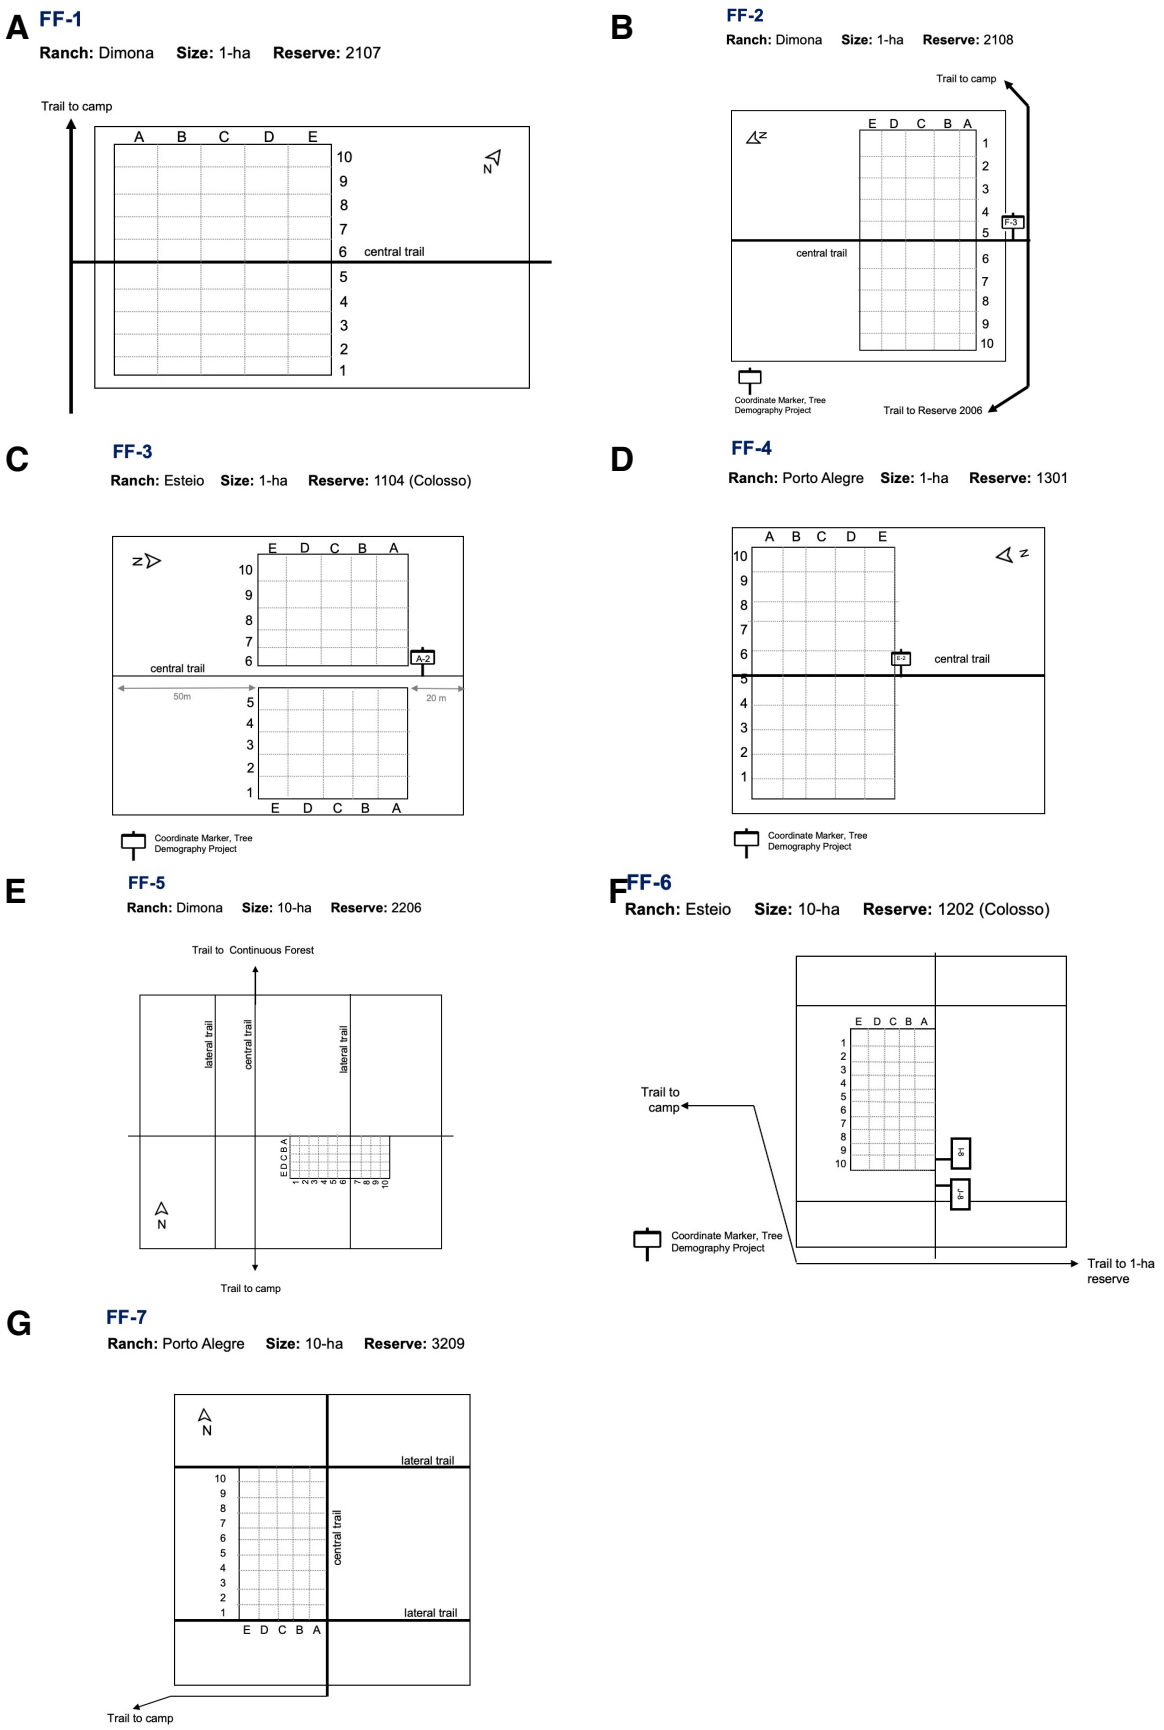

Figure 2. Schematic of the orientation and layout of each *Heliconia* Demographic Plots in Forest Fragments.

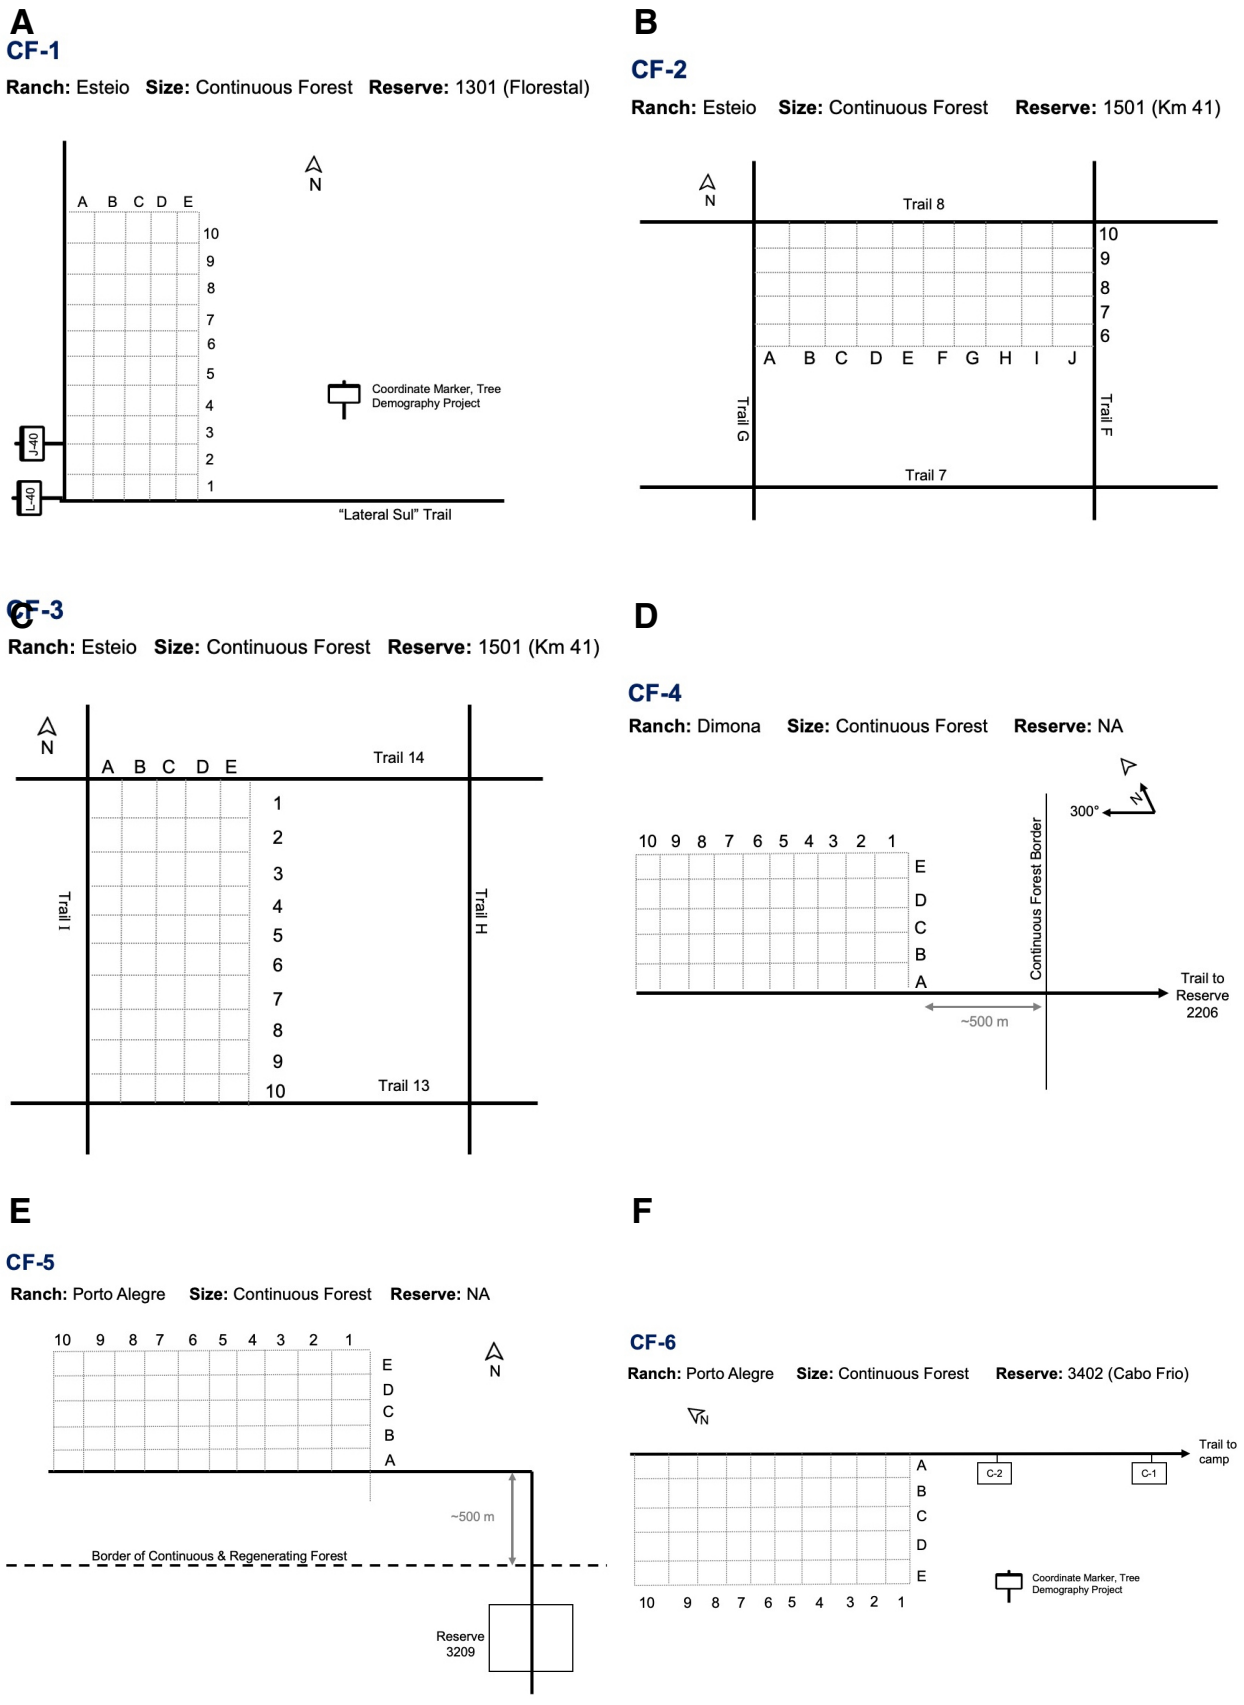

Figure 3. Schematic of the orientation and layout of each *Heliconia* Demographic Plot in Continuous Forest.
